Presented by the American Foundation for Donation and Transplantation

Overview

- HLA eplets
 - Premise
 - State of field
 - Potential application
 - Health Disparities

Lim *Kid Int* 2017

Structure and Polymorphism of HLA

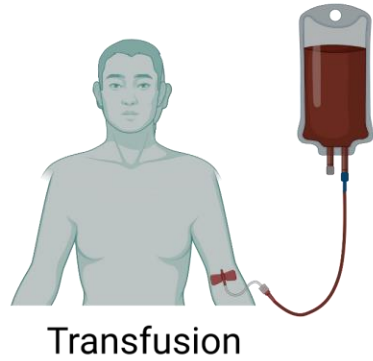

- HLA molecules present peptides to T cells
- HLA class I is formed by a continuous polypeptide encoded by one gene
 - Expressed on every nucleated cell
- HLA class II proteins are heterodimers formed by the gene products of alpha (α) and beta (β) genes
 - Only expressed on antigen presenting cells and activated/inflamed cells like endothelium

Numbers of HLA Alleles

HLA Class I Alleles	25,228
HLA Class II Alleles	10,592

Sources of HLA Allosensitization

immunizing antigen

Other documented routes:

- ❖ Homograft (cardiac repair)
- ❖ Skin grafting
- ❖ Allogeneic cell therapy

Nonsensitizing clinical events:

- ❖ Immunization
- ❖ Infection
- ❖ Surgery
- ❖ Changes in immunosuppression

What are HLA Eplets?

HLA eplets are amino acid residues that are different between two alleles, that *may* represent a target for an antibody or T cell

Tambur and Claas AJT 2015

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

Clinical Utility of HLA Eplet Mismatching

14th Annual Living Donation Conference
Presented by the American Foundation for Donation and Transplantation

HLA Eplet Mismatching: Keep in mind

Multiple algorithms

- ❖ Some *in silico*, others based on antibody verification
- ❖ Literature is a mix of approaches
- ❖ No consensus yet on which is the “best”

Requires high resolution typing

- ❖ Can be imputed from intermediate but imperfect accuracy, especially in non-Europeans [Engen *AJT* 2021]
- ❖ Larger studies from SRTR are based on imputation

Thresholds and relative risk are not fully defined

- ❖ How many is too many?
- ❖ Which mismatches are worse?
- ❖ Which outcome is more important?

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

Clinical Utility of HLA Eplet Mismatching

Improving access to transplant

Pre-transplant

- equitable access
- DSA cross-reactivity
- unacceptable antigen

chance of finding a compatible donor for highly sensitized patients based on 0-2 triplet mismatches was much higher compared to matching on the antigen level [Duquesnoy *Transpl* 2003]

reduced transplant wait time for highly sensitized patients by 50% with comparable outcomes as non-sensitized patients [Eurotransplant; Lemieux *Int Immuno* 2021; Heidt *Transpl* 2019]

eplet based method of antibody analysis had a very high degree of correlation with cell-based crossmatches [Norin *Hum Immun* 2022]

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

Improving post-transplant outcomes

DR or DQ eplet mismatch was significantly correlated with production of **dnDSA** to that locus (OR 2.50 and 2.00 per 10MM) [Wiebe *JASN* 2017]

antibody-verified eplet mismatch load was associated with any type of **rejection**; but no threshold below which the risk of dnDSA occurrence was absent [Senev *JASN* 2020]

low-immunological risk recipients (0-2 ABDR mismatched kidneys) but with high eplet mismatches (≥ 20) had 2-fold increased **risk of acute rejection** [Nguyen *Transpl Dir* 2016]

significant relationship between eplet mismatches and **graft failure**; greater effect in unsensitized recipients [Sapir-Pichhadze *Kid Int* 2020]

discriminative performance for **graft failure** was low [Senev *JASN* 2020]

after dnDSA development in kidney transplant recipients, eplet mismatches did not correlate with ABMR or allograft loss [Wen *Hum Immun* 2021]

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

Tailoring immunosuppression based on risk

Post-transplant

- immunosuppression optimization

in CTOT-09 DQ mMM (>17) predicted dnDSA on **TAC minimization** despite patients being “low risk” (per sensitization) first 6 months post-transplant [Hricik *JASN* 2015]

recipients with high eplet mismatch load were **less likely to tolerate low tacrolimus** levels without developing de novo DSAs [Davis *AJT* 2021]

patients with high-risk DQ eplet mismatch score more frequently developed **acute rejection**, even if no pre-formed T cell alloimmunity was detected [Bestard *AJT* 2021]

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

Proposed Risk Stratification Model

Pretransplant donor-recipient HLA laboratory evaluation

CDC crossmatch	Flow crossmatch	Single antigen bead	History of sensitization	HLA molecular MM	HLA identical	Immune risk assessment	
DSA positive	DSA positive	DSA positive	<p>“There is a body of evidence in support of the utility of HLA mMM score as a basis for primary alloimmunity risk stratification”</p>			Active memory and at risk for hyperacute rejection	
Negative	DSA positive	DSA positive				Active memory and at risk for ABMR and TCMR	
Negative	Negative	DSA positive				Active memory and at risk for ABMR and TCMR	
Negative	Negative	Negative		Pregnancy or prior transplant with repeat MM			At risk for latent memory with a recall B and T cell response
Negative	Negative	Negative		cPRA with unknown repeat MM			Potential risk for latent memory with a recall B and T cell response
Negative	Negative	Negative	No	High		Increased risk for de novo alloimmune response	
Negative	Negative	Negative	No	Low		Baseline risk for de novo alloimmune response	
Negative	Negative	Negative	No	0	Yes	Low risk for de novo alloimmune response	

MM, Mismatch; DSA, donor-specific antibody; ABMR, antibody-mediated rejection; TCMR, T cell-mediated rejection.

Proposed prognostic and predictive biomarker for clinical trials (under review by FDA)

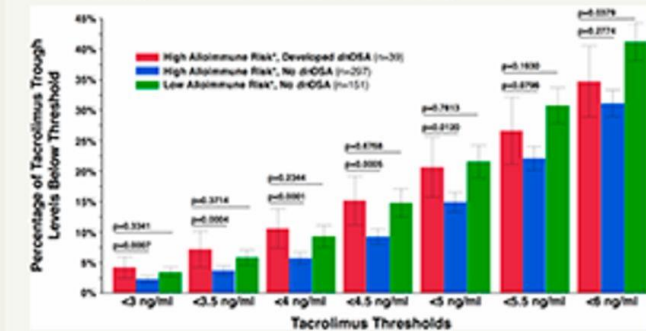

The FDA Center for Drug Evaluation and Research agreed to evaluate the potential role of HLA-DR/DQ eplet mMM score as a strategy for **enrichment or risk stratification** in phase 2 and 3 kidney transplant clinical drug development trials and as a **prognostic biomarker** for de novo DSA, graft rejection, and graft failure.

Class II Eplet Mismatch Modulates Tacrolimus Trough Levels Required to Prevent Donor-Specific Antibody Development

METHODS

- 596 renal transplant recipients
- 50,011 serial tacrolimus trough levels
- HLA-DR/DQ eplet mismatch determined using HLAMatchmaker software
- The frequency of tacrolimus trough levels below a series of thresholds <6 ng/ml and the mean tacrolimus levels prior to *dn*DSA development were analyzed in the context of HLA-DR/DQ eplet mismatch

OUTCOME Risk of *de novo* DSA development was effected by HLA-DR/DQ eplet Mismatch and tacrolimus trough levels

CONCLUSIONS HLA-DR/DQ eplet mismatch and tacrolimus trough levels are independent predictors of *dn*DSA development. Recipients with high HLA alloimmune risk should not target tacrolimus levels <5 ng/ml unless essential and monitoring for *dn*DSA may be advisable in this setting.

Equitable allocation and addressing health disparities

Table 4. Actual Number of Graft Failures in 2000 and Number Expected If Matching for HLA-B Alone or HLA-B and DR Was No Longer a Priority.*

Race	Actual No. of Graft Failures	Change Resulting from Elimination of HLA-B Matching	Change Resulting from Elimination of HLA-B and DR Matching
		<i>no. of failures</i>	
All	1779	+36	+142
White	1057	+21	+85
Black	631	+13	+51
Other	91	+2	+7

* Calculations are based on random matching of donors and recipients with compatible blood types. The rates are for graft failures occurring in 2000 after transplantation between March 6, 1995, and June 30, 2001. The average duration of follow-up was 2.7 years. One- and three-year rates of graft survival for the entire group were 87.2 percent and 77.1 percent, respectively. The relative risk of graft failure was 1.02 (P<0.001) with the elimination of HLA-B matching as a priority and 1.08 (P<0.001) with the elimination of HLA-B and DR matching as a priority, as compared with keeping the current allocation policy.

Roberts NEJM2004

Bekbolsynov Front Immun 2022

Higher rates of antigen-level mismatching in non-European recipients

Models eliminating antigen-level matching predicted increased rates of transplantation for non-European ancestry patients ...but quite offset by greater risk of rejection

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

Enhancing HLA matching for non-European patients

the current allocation system inadvertently matches Black patients to donors with significantly higher immunogenic transplants compared to other races

using race-adjusted immunogenicity thresholds in allocation would result in a net gain of thousands additional kidney life-years for all races [Bekbolsynov *Front Immun* 2022]

Pre-transplant

- equitable access
- DSA cross-reactivity
- unacceptable antigen

Post-transplant

- rejection risk
- dnDSA risk
- graft longevity

HLA class I eplet load greater than 70 resulted in a greater risk of rejection in the race-mismatched pediatric transplants vs. race-matched [Philogene *Ped Nephrol* 2019]

14th Annual Living Donation Conference

Presented by the American Foundation for Donation and Transplantation

NATIONAL KIDNEY REGISTRY[®]
FACILITATING LIVING DONOR TRANSPLANTS

Precise Technology to Find You the Best Match

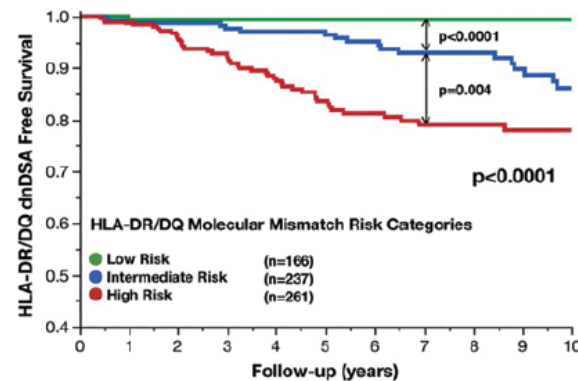

Traditionally, transplant matches were measured by an HLA match score from 0-6 (6 being the best). HLA scores are generally based on A, B and DR antigens. An antigen mismatch is where rejection often starts.

Wiebe C, Kosmoliaptsis V, Pochinco D, et al. HLA-DR/DQ molecular mismatch: A prognostic biomarker for primary

By minimizing eplet mismatches and understanding the match they receive, a recipient can potentially:

- a) reduce the risk of de novo DSA formation
- b) lower the probability of rejection
- c) lower the probability of graft failure
- d) lower their immune-suppression dosage

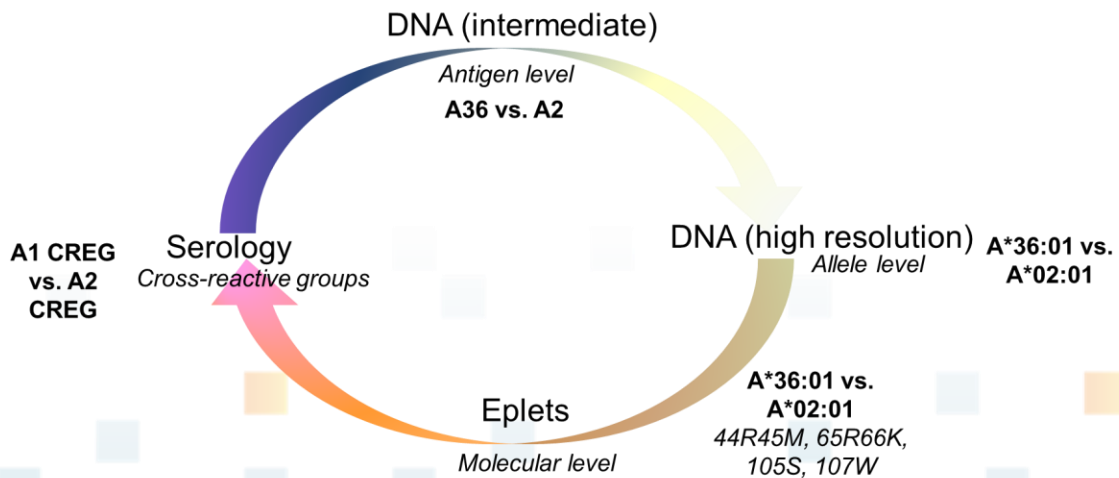

Wiebe C, Kosmoliaptsis V, Pochinco D, et al. HLA-DR/DQ molecular mismatch: A prognostic biomarker for primary alloimmunity. *Am J Transplant.* 2019;19:1708-1719.

NKR is currently employing high-resolution genotyping to improve molecular matching and blood typing (for A subtyping), and these efforts may be particularly important for compatible pairs entering paired exchange.

ion Conference

Presented by the American Foundation for Donation and Transplantation

Current Consensus on HLA eplet mismatching

1. Approaches need to be optimized and algorithms standardized and locked before implementation in clinical practice.

2. Thresholds for risk categories need to be established and the impact of other factors on these thresholds need to be accounted for. Formal evaluation, in prospective clinical trials, should be performed.

3. Tools to prospectively determine donor/recipient HLA specific **immunogenicity** beyond the mismatch load (given that DSA can be developed in some patients with low HLA mMM score) should be developed.

4. This is essential before considering evaluation and implementation of immunogenicity analysis as a guide to organ allocation schemes.
